Role of wild boar in the transmission of ASF, CSF and FMD in Eurasia

- ❖ FMD incursion to Bulgaria (2011)
- ❖ CSF outbreaks in Latvia and Lithuania and other European countries (2011-2013)
- ❖ ASF epidemic in the Caucasus, Russian Federation, Lithuania, Latvia, Poland and Estonia (2007-2015) - still ongoing
- ❖ remarkable increase of wild boar populations in Europe

Wildlife surveillance

- ❖ Wildlife surveillance mostly linked to hunting
- ❖ Sampling rather irregular
- ❖ Hunting seasonally limited
- ❖ Rarely adequate number of samples collected
- ❖ Mostly serological tests performed - only retrospective analysis

Solution: Non-invasive sampling of wild boar?

Advantage of non-invasive sampling:

- Independent of hunting (access to areas where hunting is limited/prohibited)
- Collective sample: Disease detection on basis of herds
- No disturbance of natural behaviour

pSWAB material

Cotton ropes, native (without treatment), 10 cm length, 8 mm
Matrix: Cereal based with „marzipan flavor“ (CSFV vaccine bait, IDT Dessau)

All pictures: Susan Mouchantat

CSF vaccine baits for wild boar

Toxicity test:

- Native cotton rope no impact on virus stability (Mouchantat et al., unpublished)

Saliva volume capacity:

Varies by size of animal, 1-2,65 ml

Experimental infection of wild boar with ASF

Arch Virol (2015) 160:1657–1667
DOI 10.1007/s00705-015-2430-2

ORIGINAL ARTICLE

Course and transmission characteristics of oral low-dose infection of domestic pigs and European wild boar with a Caucasian African swine fever virus isolate

Jana Pietschmann¹ · Claire Guinat² · Martin Beer¹ · Valery Pronin² · Kerstin Tauscher³ · Anja Petrov¹ · Günther Keil⁴ · Sandra Blome¹

Experimental study: 17 days

<i>Animals</i>	6 wild boar (8 Mo, ≈ 15 kg)
<i>Inoculation</i>	oronasal 100 HAU / ml (Minimum dosis) Armenia/08
<i>pSWABs</i>	max. 10 distributed (DPI 3-8 and DPI 16+17) collected next days
<i>Collection blood/oropharyngeal sample</i>	every 2 days under sedation
<i>Diagnostic</i>	qPCR, serology

CSF experimental infection in domestic pigs

In the field - non infected area

- Distribution of pSWABs at two locations
 - Recovery rate depending on day of collection:
 - Up to 100% when collection following day
 - decreasing recovery rate with every day (<50% after 4 days)
 - Ropes sometimes on the paths of wild boar far from distribution site: needs systematic search

Development of a Triplex qPCR for simultaneous detection of swine-specific and ASF genome combined with internal control

Primer design for *Sus scrofa* specific target gene regions of CEACAM18 and mtCytB with ActB as control (Mouchantat, Forth, Kammerer et al., in preparation)

In the field - ASF-infected area

- Collaboration with Estonia and Latvia
- Project ongoing: Distribution of pSWABs in Estonia, collection and investigation in the laboratory
- Applicable where/when hunting is not possible
- Suitable for ASF-antibody detection? (In process)

Summary

Material

- pSWAB well accepted by wild boar -> collective sample of a wild boar herd
- The rope is robust, has a high capacity to absorb saliva, is easily produced, cost-effective and logistically simple to integrate into wildlife management practices
- pSWAB is virus stable and is generally suitable as a rope-in-a-bait

Suitability for virus detection

- Four experimental infections of wild boar with ASF (2), CSF and FMD proved the suitability of the pSWABs in vivo
 - Detection on herd basis as long as there is virus shedding by saliva even when shedding period is very short, viral load in saliva is low and animals do not exhibit any clinical signs.

Suitability in the field

- pSWAB is chewed on by wild boars at feeding or wellness places (disadvantage: also other animals take them (away))
- In infected areas: first results from Estonia
- Can be useful in areas with no or prohibited hunting

Hypotheses (2014):

1. ASF will fade out
2. ASF moves rapidly westwards

One year later.....

Both hypotheses proved to be more or less wrong

- No fading out
- No rapid westward movement

=> Established in the region

What we know

Lethality is high (>90%)

(number of deaths / number of infected x 100)

Mortality is low (<5%)

(number of deaths / population x 100)

Prevalence low (<5%)

(number of infected / population x 100)

Contagiosity is low

(slow spreading.... Takes time)

-> **direct contact** with infected material (blood/meat) or sick/dead animals

A low dose may not lead to an infection of healthy wild boar

Klaus Depner

ASF VIRUS IS VERY STABLE

- 140 days in Iberian and Serrano hams
- 399 days in Parma ham
- 112 days in Iberian pork loins.
- 18 months in pig blood at 4°C
- 11 days in faeces at 20°C
- Possibly long time in carcasses (dead animals) which decompose

- Do wild boar get into contact with dead wild boar and after how long time does this happen?
- Contact randomly or targeted?
- Which animals get into contact (age group)?

- What kind of contact (nibbling, tearing, eating)?
- Real cannibalism between wild boar?
- How long is a carcass interesting for wild boar? Do they eat larvae?

Hypothesis

ASF is a carcass-borne disease with infected carcasses as the virus reservoir

- May explain the virus persistence in geographical areas and the low prevalence (5%)
- If so: safe disposal of carcasses may be the key to success for the eradication of ASF (using sniffer dogs?)
- Investigation of wild boar populations and their behaviour to dead wild boar of different ages at different places and to different seasons will provide more insights on the epidemiology of ASF in wild boar populations
